### Overview

Gunicorn is a type of Web Server Gateway Interface (WSGI) HTTP server.

### WSGI

There are many different frameworks that are available for Python to develop web applications, because of this compatibility issues arise. WSGI provides a specification ([PEP 3333](#)) to adhere to, making any servers that use it compatible with any frameworks that also use it.

### Pre-fork Worker Model

Gunicorn uses a pre-fork worker model which is a master process which controls 1 or more worker processes:

- The master process knows nothing about the client connections to the worker processes.
- Process signals are sent between the workers & master to determine whether a new worker needs to be booted.
- If a worker process crashes from a fatal exception, then another worker can be booted to replace it.

### Installation

Gunicorn can be installed by using `pip`:

```
pip install gunicorn
```

### Usage

You can start an application by running the command below, this would work for an application written in a file called `app.py` with the application set to an `app` variable:

```
# gunicorn [APP_MODULE]:[VARIABLE_NAME]
gunicorn app:app
```

- **APP\_MODULE**  
This is will be the module (Python file) that the application is in.
- **VARIABLE\_NAME**  
By default, Gunicorn will look for a variable called **application**, if yours is defined as something else then it may be specified here.

## Workers

The amount of workers can be specified with the **-w** or **--workers** options. The Gunicorn documentation recommends that you use 2-4 workers per core the server you are using has:

```
# gunicorn --workers [NUMBER] app:app
gunicorn --workers 4 app:app
```

## Specify Server Socket to Bind to

You may provide a server socket in the form of **[HOST]** or **[HOST]:[PORT]** with the **-b** or **--bind** options.

To allow traffic from anywhere on port **8001** you can use the following:

```
# gunicorn --bind=[HOST]:[PORT] app:app
gunicorn --bind=0.0.0.0:8001 app:app
```

## Working Directory

Gunicorn can operate in a specified directory using the **--chdir** option, this would typically be the application root:

```
# gunicorn --chdir=[DIRECTORY] app:app
gunicorn --chdir=/opt/project app:app
```

## Tutorial

### Run a Simple Flask Application with Gunicorn

#### Prerequisites

- Linux Operating System (Debian 9/Ubuntu 18)
- Python 3
- **virtualenv**

These prerequisites can be setup using the following commands:

```
sudo apt update
sudo apt install -y python3 virtualenv
```

#### Create an Application Folder

Create a folder for the test application and change to it

```
mkdir -p gunicorn-test && cd $_
```

#### Create the Application

This is going to be a very simple application which uses the Flask framework. Enter the following into a file called **app.py** and save it:

```
#!/usr/bin/env python
from flask import Flask
app = Flask(__name__)

@app.route('/')
def hello():
    return "Hello from Flask App\n"

if __name__ == '__main__':
    app.run()
```

## Create a Virtual Environment and Install the Dependencies

We will be needing the `flask` and `gunicorn` dependencies for this.

A virtual environment can be created and loaded:

```
virtualenv -p python3 venv
source ./venv/bin/activate
```

And then the required dependencies can be installed in the aforementioned virtual environment:

```
pip install flask gunicorn
```

## Run the Application

The application can now be started using a gunicorn command:

```
gunicorn --workers=4 --bind=0.0.0.0:5000 app:app
```

Something similar to this should be outputted:

```
[2019-12-04 15:58:37 +0000] [3006] [INFO] Starting gunicorn 20.0.4
[2019-12-04 15:58:37 +0000] [3006] [INFO] Listening at: http://0.0.0.0:5000
(3006)
[2019-12-04 15:58:37 +0000] [3006] [INFO] Using worker: sync
[2019-12-04 15:58:37 +0000] [3009] [INFO] Booting worker with pid: 3009
[2019-12-04 15:58:37 +0000] [3010] [INFO] Booting worker with pid: 3010
[2019-12-04 15:58:37 +0000] [3011] [INFO] Booting worker with pid: 3011
[2019-12-04 15:58:37 +0000] [3012] [INFO] Booting worker with pid: 3012
```

## Exercises

### Try this on Another Project

Use another Python Flask application and run it using Gunicorn just like in the tutorial above.

If you don't have a Flask app available to you then feel free to use this [provided example](#).
